Possible strategies for locating ncRNA genes in genomic sequences

- ★ Sequence similarities
- ★ Comparative genomics
- ★ Transcription signals
- ★ Statistical analysis
- ★ blabla

RNA interference

- ★ sequence specific, post-transcriptional gene silencing
- ★ induced by double-stranded (ds) RNAs
- ★ only a small portion of siRNAs designed for any gene is effective.

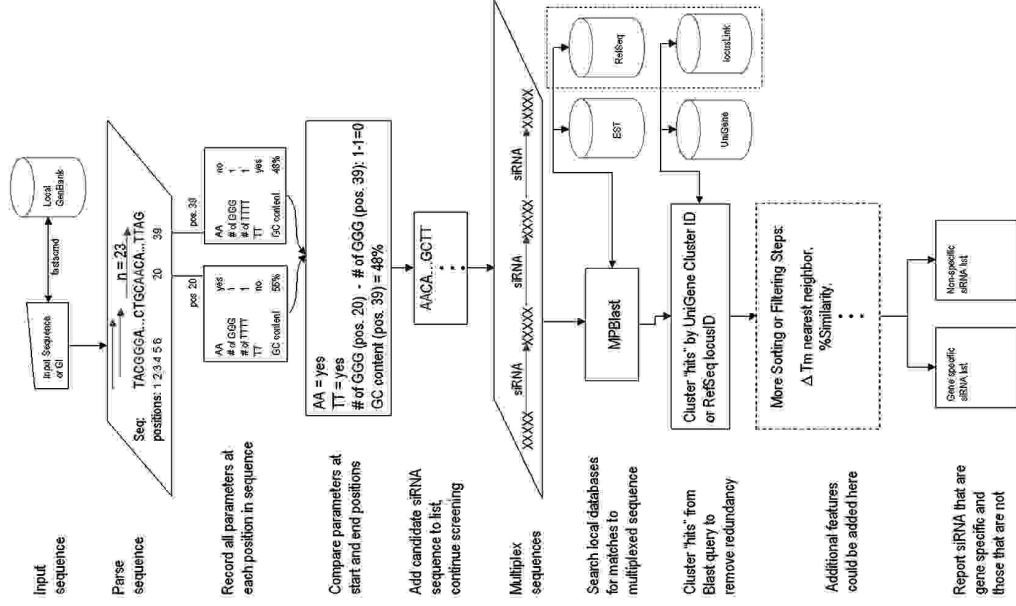

Empirical rules for siRNA design

category	features	autors
Length	duplexes, length 21 (default) to 23 nt	all
Sequence	G/G content (30% to 70%) location of mismatches no homopolymers longer than 3 bases Remove sequences with tandem repeats	all A A, D, Q G
Overhangs	2-nt symmetric 3' overhang (TT) nucleotide content of the 3' overhangs	T,Q A
Motives	NAR(N17)YNN * AA(n19)	T A, D, Q
Specificity	blast-search against EST libraries	all
Thermodynamics	TM	A, G
Structure	no strong internal secondary structure	D, G

* where R is purine (A, G) and Y is pyrimidine (C, U)

A Ambion, T Tuschl, Q Qiagen, D Dharmacon, G GenScript

Data flow

Characteristics associated with siRNA functionality

feature	authors
low G/C content	1 (30-52%),
bias towards low internal stability at 3'end	1, sense strand
lack of inverted repeats in siRNA	1,
sense strand base preferences (pos.3,10,13,19)	1,

base preferences:

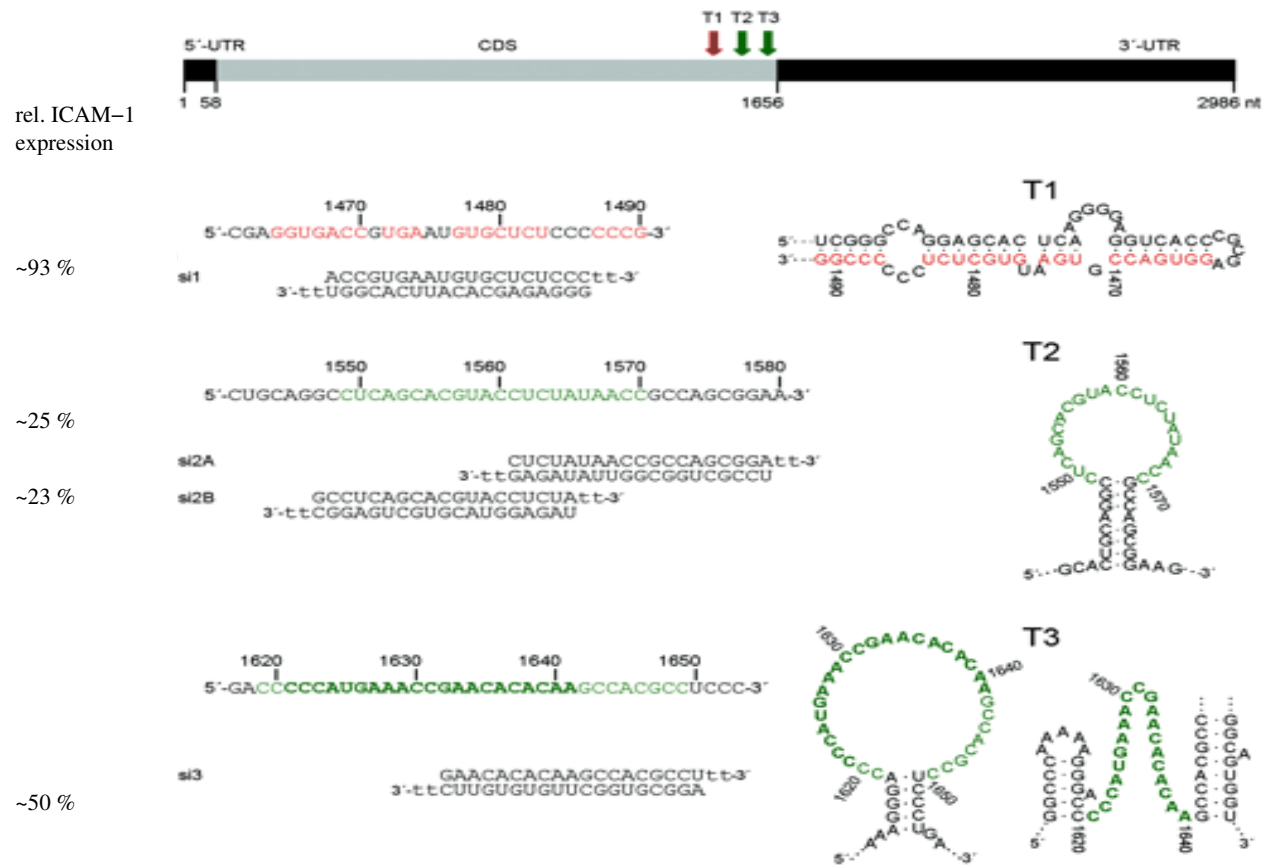

pos.3 is A:

pos.10 is U: RISC cleaves mRNA between position 10 and 11 of relative to the 5' end of the complementary target strand, most endonucleases prefer to cleave 3' of U

pos.13 is no G:

pos.19 no GC, is A:low internal stability of the sense 3' end, promote strand selection and entry into RISC. 75% of miRNA precursors contain U at pos.1 (corresponding to A in pos.19 of siRNA sense strand)

Target mRNA secondary structure and accessibility
