Duplication

Insertion

Pseudogenization

Evolution of eukaryotic tRNAs II

Remolding

Mutation inside the anticodon such that the tRNA identity changes

Evolution of eukaryotic tRNAs II

Remolding

Mutation inside the anticodon such that the tRNA identity changes

Alloacceptor
anticodon change

Evolution of eukaryotic tRNAs II

Remolding

Mutation inside the anticodon such that the tRNA identity changes

Alloacceptor
anticodon change

Isoacceptor
anticodon change

- tRNA genes act as repetitive elements
 - loss of tRNAs leads to large differences in the tRNA complements
 - reconstruction of the history of a gene family is not possible with common methods
 - reciprocal best match
 - phylogenetic tree-based
- **Aim:** create a framework to distinguish paralogs and orthologs in gene families of related species

1. Annotation of tRNAs

→ tRNA gene detection in genome sequences applying tRNAscan-SE

- It is able to detect ~99% of eukaryotic nuclear tRNA genes
- 5 primates and human
- 12 drosophilids

2. Determine anchors of tRNAs

1) MSA block based approach

→ Sequence-unique MAF blocks of `multiz` alignments

Step-wise orthology identification

2. Determine anchors of tRNAs

I) MSA block based approach

→ Sequence-unique MAF blocks of multiz alignments

II) Orthologous proteins approach

→ 1 : 1 set of orthologs

→ Linear coordinate interpolation

$$t^* = p^b + \frac{q^b - p^b + 1}{q^a - p^a + 1} t^a$$

Step-wise orthology identification

2. Determine anchors of tRNAs

I) MSA block based approach

→ Sequence-unique MAF blocks of multiz alignments

II) Orthologous proteins approach

→ 1 : 1 set of orthologs

→ Linear coordinate interpolation

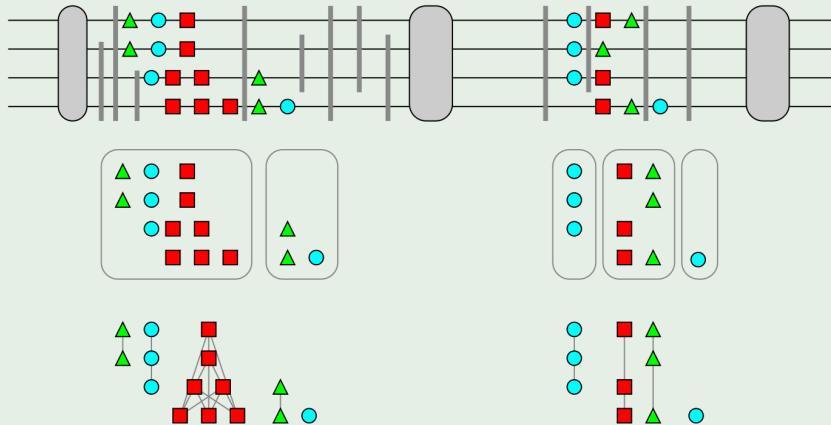

Step-wise orthology identification

3. Clustering of tRNAs based on anchors

Step-wise orthology identification

4. Orthology reconstruction

4. Orthology reconstruction

→ Generalized list alignments

Ptr	-	-	-	-	-	V	~	V	~	R	~
Hsa	-	-	-	-	-	V	~	V	~	R	~
Ggo	-	-	-	-	-	V	~	V	~	R	~
Pab	F	F	K	K	L	V	V	V	V	R	R
Nle	-	-	-	-	-	V	~	V	~	R	~
Mmu	F	F	K	K	L	V	~	V	~	R	~

Step-wise orthology identification

4. Orthology reconstruction

Gain, loss and duplications of tRNAs in primates (MSA)

- 482 singeltons
 - 64 tRNAs of a single species
 - 327 cliques, without duplications
 - 206 including duplications
- $\frac{2}{3}$ syntenically conserved tRNAs

Gain, loss and duplications of tRNAs in primates (OP)

- 231 genomic clusters of tRNAs, of which 166 are nontrivial
- Less numbers of evolutionary events detectable

Comparison of the different methods

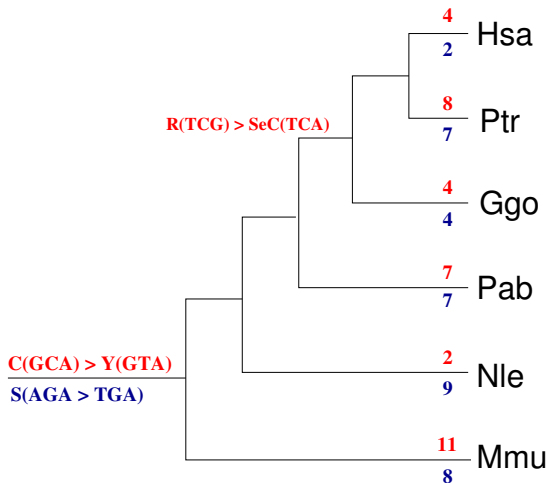

- Number of clustered tRNAs

Comparison of the different methods

- Number of ortholog edges
- 83% of the edges of MSA are recovered with PO

Remolding events in primates (MSA)

- Alloacceptor (red), isoacceptor (blue)
- Most remolding events constitute pseudogenes

- Created significant methods to detect phylogenetic events on tRNAs
- MSA is sensitive for predictions of remodeling events
- Remolding events mostly occur in pseudogenes
- A large number of gain and loss of tRNAs are species specific
